

Introduction to Git

EDH7916

Benjamin Skinner

From the git website <http://git-scm.com/>

Git is a free and open source distributed version control system designed to handle everything from small to very large projects with speed and efficiency.

Why use git?

With so many other (read: easier!) ways to share and collaborate on documents, why use git? Isn't it a bit overkill to learn an entirely new syntax? Why not just email files or use something like DropBox? Because it is very easy to end up with something like this:

As complexity increases, so does the need for git

$$\text{Project} = f(\text{size}, \text{scope}, \text{collaborators})$$

As any part of that function grows, so too does the need for a work flow that:

- Allows for many moving parts
- Allows for peaceful collaboration (no overwrites)
- Allows for timely collaboration (synchronous)
- Allows for distant collaboration (centralized file location)
- Allows for version control (so you can go back if necessary)

Git was designed to do all these things, so it works better than other systems.

What's the difference between git and GitHub?

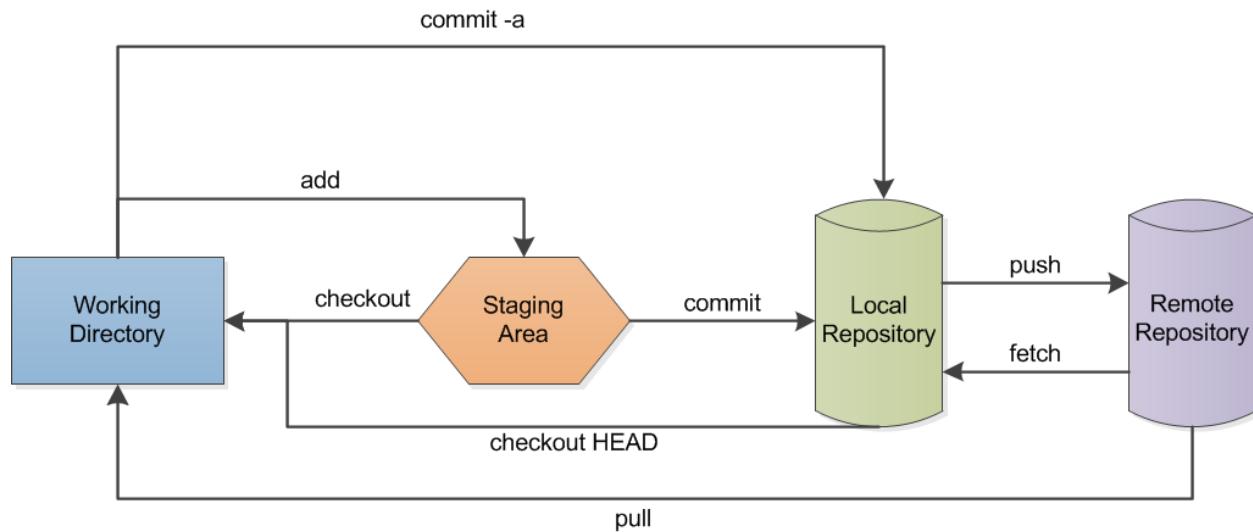

Yep, you guessed it. Git is the system/language that supports version control. GitHub is an online service that will host your remote repositories, for free if public or a small fee if private. (Students get an education discount and some free repos. Check out <https://education.github.com/>.)

RStudio is nice because it provides a nice point-and-click interface for git. (Sourcetree² and GitHub Desktop³ are also really nice GUIs.) If you want to run git at the command line, go for it! But using RStudio or another GUI is fine.

²<https://www.sourcetreeapp.com>

³<https://desktop.github.com>

How does git/GitHub work?

commit -a: Directly commit modified and deleted files into the local repository (*no new files!*)

add: Add a file to the staging area.

checkout: Get a file from the staging area.

checkout HEAD: Get a file from the local repository

commit: Commit files from the staging area to the local repository

push: Send files to the remote repository

fetch: Get files from the remote repository

pull: Get files from the remote repository and put a copy in the working directory

4

Credit: Lbhtw (Own work)

Plain text and git

Git works best with plain text files⁵. This is because it notes the differences across two plain text files rather than just copying and re-copying the same file over and over again as it changes. When you've only changed one word, git's method of version control is much more efficient than making a whole new copy.

It's also useful when you need to merge two files. If file B is just file A with new section, file B can be easily merged into file A by inserting the new section — just like you would add a paragraph in a paper you're writing. R scripts are plain text. Some data files, like *.csv, are plain text. This is why git works really well with data analysis workflows.

On the other hand, git does not work as well with binary files⁶. These files are stored in a format closer to what your computer understands, which comes with benefits. Data files, like Stata's .dta and R's .Rdata, as well as MS Office files — .docx, .xlsx, *.pptx, etc — are binary files. Git will keep track of your MS Word document, but due to its underlying structure, you won't be able to merge and every small change will just make a whole new copy of the file. This is why we generally don't commit large binary data files to Git: your repo just becomes larger and larger with each small change to your data.

⁴https://commons.wikimedia.org/wiki/File:Git_data_flow.png

⁵https://en.wikipedia.org/wiki/Plain_text

⁶https://en.wikipedia.org/wiki/Binary_file

Some notes on work flow (good habits)

1. Always `pull` from your local repo with your remote repo before starting any work. This makes sure you have the latest files. RStudio has a `pull` button in the **Git** tab.
2. Don't wait to `push` your commits. Just like you save your papers every few lines or paragraphs, you should push to your remote repo. This way, you're less likely to lose work in the event of a computer crash. Also, should you want to return to a prior version, small changes make it easier to find what you want.
3. Add useful `commit` messages. RStudio will make you add something. Don't say "stuff." A version history of 95 "stuff"s is pretty non-helpful. Also, I would keep it clean. Even in a private repository, work as if someone will see what you write someday.
4. Don't freak out! If you accidentally push and overwrite or delete something on the remote, you can get it back. That's the point of version control! Sometimes weird things like merges happen (two files with the same name are shoved together). They can be a pain to fix, but they can be fixed.
5. Avoid tracking overly large files and pushing them to your remote repository. GitHub has a file size limit of 100 MB per file and 1 GB per repo. The history of large files compounds quickly, so think carefully before adding them. Usually this means that small data sets are okay; big ones are better backed up somewhere else and left on your machine.
6. Remember: even in a private repository, your files are potentially viewable. If any of your data sets or files are restricted, do no push them remotely. Use `.gitignore` to make sure that git doesn't track or push them.

Every class and work session should go like this:

1. `pull` from GitHub remote
2. *do work*
3. `add` or `stage` (if new file)
4. `commit` with message
5. `push` back to GitHub remote

If you'd like you can also use terminal commands to accomplish the same things. Many people (including me) like to use the terminal commands directly.

- Pull: `git pull`
- Stage: `git add <filenames>`
- Commit: `git commit -m "<your message here>"`
- Push: `git push`

That said, you should use whatever works best for you.

Getting your class repo and linking with git

In this class, you'll work in and submit your work through a private git repository that only you and I will be able to access. I've already set that up in our course organization on GitHub. Let's get your repo onto your computer.

Step 0: Install git on your computer

Follow these directions to install git on your computer⁷, if you need it and haven't already done so. If you use a Mac, there's a good chance you already have git on your machine. You can check by opening the Terminal application and typing `which git` at the prompt. If you get a response like `/usr/bin/git` then you have git. It's unlikely to be the newest version, but is probably good enough for our class. That said, it generally doesn't hurt to install a newer version.

⁷[%7B%7Bsite.baseurl%20%7D%7D/software](#)

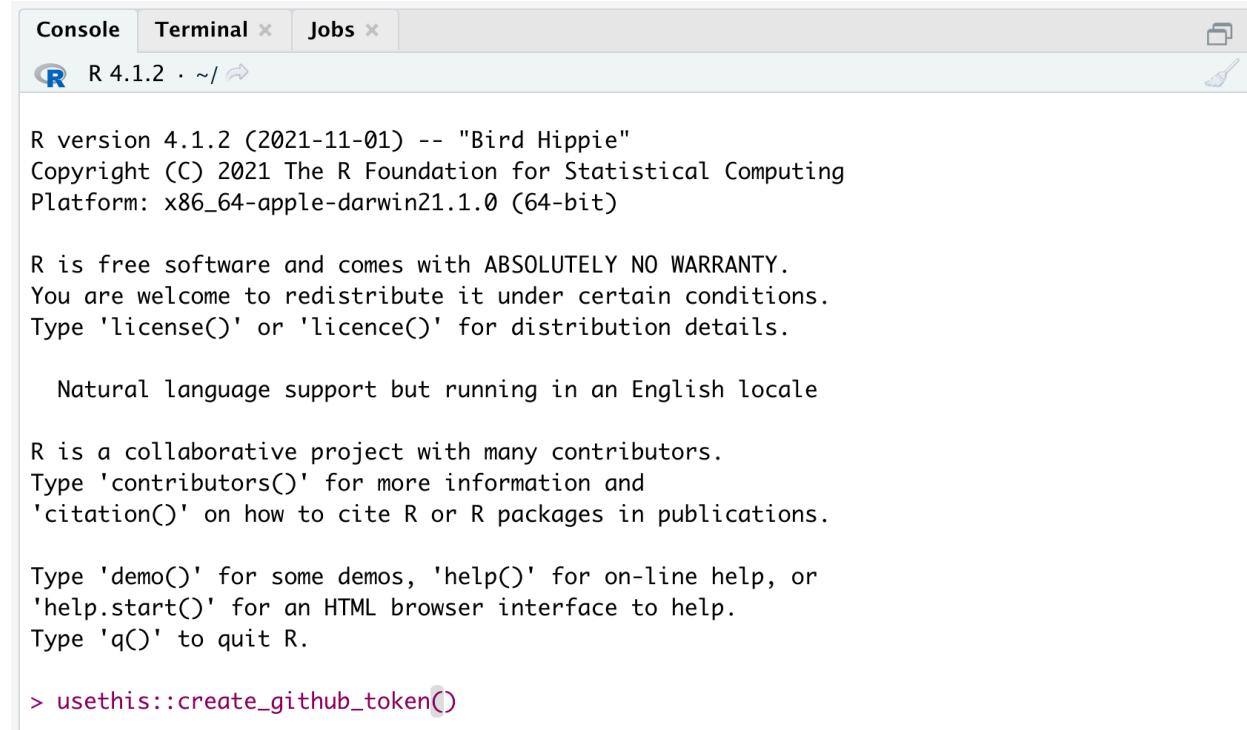

Step 1: setting a personal access token or PAT

Before we try to use git through RStudio, we need to set up your GitHub user credentials on your computer. This is a security feature of GitHub that prevents others from accessing your account. Think of a personal access token or PAT as a special type of password that links your computer to GitHub and that can be set with different levels of permission on your account. It can be very limited, allowing the computer user only a very number of options or very broad, giving the computer user a many ways to interact with GitHub. It can also be set to expire if you want.

To set up your PAT, we'll once again use Jenny Bryan's GitHub guide⁸. Specifically, we'll use instructions found here⁹. Repeating the instructions, they are:

In the RStudio console, type the following and press enter:

```
usethis::create_github_token()
```

```
Console Terminal × Jobs ×
R 4.1.2 · ~/ ↗
R version 4.1.2 (2021-11-01) -- "Bird Hippie"
Copyright (C) 2021 The R Foundation for Statistical Computing
Platform: x86_64-apple-darwin21.1.0 (64-bit)

R is free software and comes with ABSOLUTELY NO WARRANTY.
You are welcome to redistribute it under certain conditions.
Type 'license()' or 'licence()' for distribution details.

Natural language support but running in an English locale

R is a collaborative project with many contributors.
Type 'contributors()' for more information and
'citation()' on how to cite R or R packages in publications.

Type 'demo()' for some demos, 'help()' for on-line help, or
'help.start()' for an HTML browser interface to help.
Type 'q()' to quit R.

> usethis::create_github_token()
```

This should open up a web page on GitHub to create a token with some presents. The presets are fine, though I would recommend setting the PAT to last at least until the course is over (so you don't have to do all of this again in a month). In this example, I put this course id in the use Note box and set the expiration for middle of the summer after the course has ended. Once you've set these, scroll to the bottom and click the button to generate the PAT.

⁸<https://happygitwithr.com/>

⁹<https://happygitwithr.com/https-pat.html#tldr>

New personal access token

Personal access tokens function like ordinary OAuth access tokens. They can be used instead of a password for Git over HTTPS, or can be used to [authenticate to the API over Basic Authentication](#).

Note

edh7916

What's this token for?

Expiration *

Custom...

07/01/2022

You see a screen that looks like this:

Personal access tokens

[Generate new token](#) [Revoke all](#)

Tokens you have generated that can be used to access the [GitHub API](#).

Make sure to copy your personal access token now. You won't be able to see it again!

✓ ghp_ [REDACTED]	Copy	Delete
-------------------	------	--------

I've blocked out the letters and numbers after ghp_ (not that I'm using this PAT since it's now public!), but you should see a full string. Keep this window open and head back to RStudio.

In the console type and press enter:

```
gitcreds::gitcreds_set()
```

```
> gitcreds::gitcreds_set()
```

```
? Enter password or token: ghp_[REDACTED]
```

It will ask you to add your password. Paste the ghp_ PAT and press enter. If it worked, you should see the following:

```
-> Adding new credentials...
-> Removing credentials from cache...
-> Done.
> |
```

If you (or someone you share your computer with) has already set up a PAT in the past, you will be given the option to keep your current set up or replace. I'll leave that to you. All else being equal, it's probably

better to replace the old PAT with the new PAT unless you have compelling reason not to do so.
You should now be set to use GitHub with class!

Step 2: clone your GitHub repo to your computer

Navigate to your GitHub repo at github.com. Once you've signed into your account, you should be able to navigate to it through GitHub's interface. Because the repos are structured the same way, you can also use this link:

<https://github.com/edquant/<...>>

Where <...> is your repo name. Unless otherwise said, it should take the form of `student_<last name>` (students with shared last names will have a slightly different repo name since repo names within the organization must be unique — ask me or check your email). For example, my repo is `student_skinner` and is found at:

https://github.com/edquant/student_skinner

If you click on this an you aren't me, you'll get a 404 error page. That's because it's a private repository, meaning only those with access can see it — GitHub pretends it doesn't exist otherwise. If you can't find your repo, double check two things:

- that you have the correct repo name (no typos)
- that you are signed into GitHub

If you are signed in and have the right link, you should see your page. For example, mine looks like this:

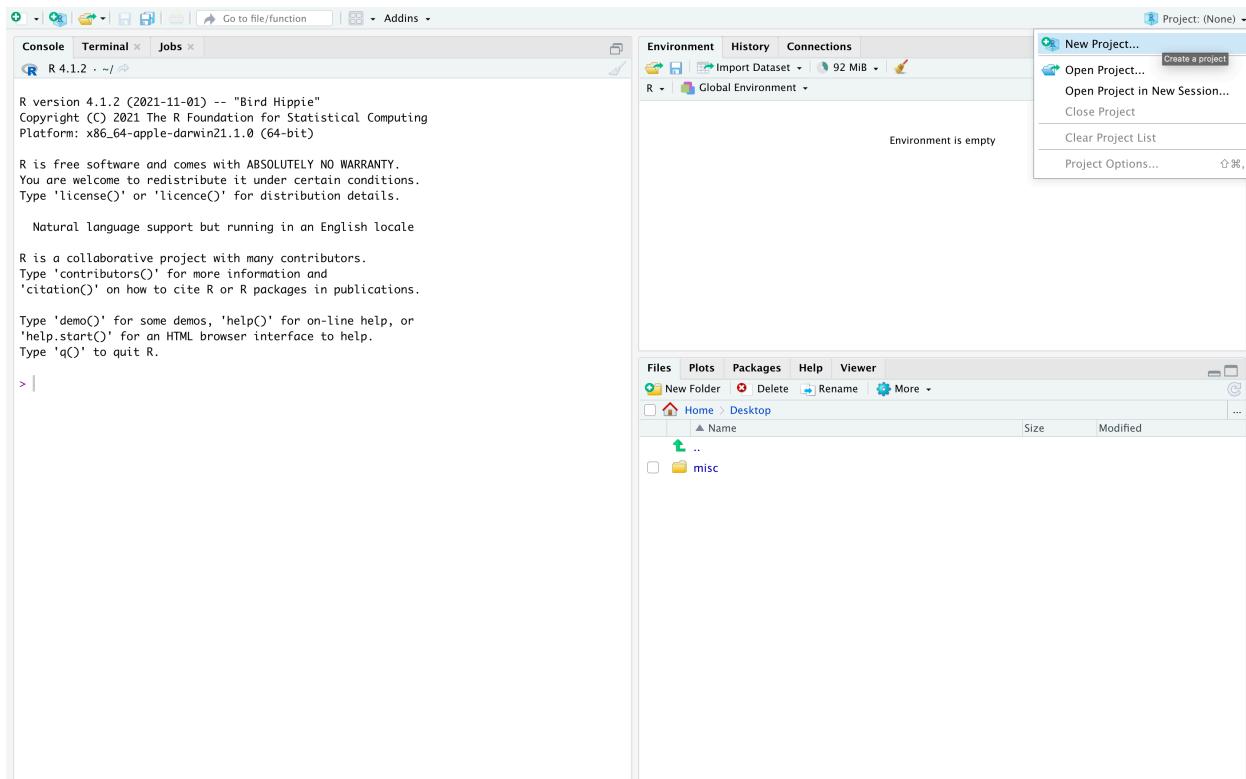

The screenshot shows a GitHub repository page for 'edquant/student_skinner'. The top navigation bar includes links for 'Code', 'Issues', 'Pull requests', 'Actions', 'Projects', 'Security', 'Insights', and 'Settings'. The main content area displays the repository's structure and activity. On the left, a tree view shows directories like 'assignments', 'data', 'final_project', 'final_project_example', 'lessons', 'scripts', 'working', '.gitignore', and 'README.md'. Each item has a timestamp indicating when it was last modified. To the right of the file list are sections for 'About', 'Releases', 'Packages', and 'Languages'. The 'About' section notes 'No description, website, or topics provided.' The 'Releases' section says 'No releases published' and 'Create a new release'. The 'Languages' section shows a single bar for Python at 100.0%. At the bottom, a note states: 'This is your personal repository for EDH 7916: Contemporary Research in Higher Education. You should have the following directory structure:' followed by a code block showing the expected directory structure.

Just above the list of files, click on the button that says clone (it's green by default).

The screenshot shows a GitHub repository page for a user named 'edquant'. The repository has 1 branch and 0 tags. A context menu is open over the repository details, specifically over the 'Clone' option. The menu includes links for 'HTTPS', 'SSH', and 'GitHub CLI', along with a copy icon and a link to 'https://github.com/edquant/student_sk'. Below the menu, there's a note about using Git or SVN, an option to 'Open with GitHub Desktop', and a 'Download ZIP' button. The repository list on the left includes files like assignments, data, final_project, final_project_example, lessons, scripts, working, .gitignore, and README.md, with their last modified times.

You'll see a drop down. Confirm that **HTTPS** is bold and underlined. You'll want to copy to the web address in the text box for the next step (you can use the overlapping box symbol just to the right of the address to copy it to your clipboard).

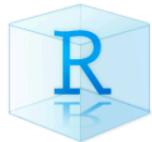

Now, return to RStudio. In the upper right hand corner, you'll see *Project: (none)* (if you've been using RStudio, you may have a project going, meaning it won't say "none", but that's okay). Click on that to see a drop down list of options. You will click on the first option *New Project*.

This window will pop up.

New Project Wizard

Create Project

New Directory

Start a project in a brand new working directory

Existing Directory

Associate a project with an existing working directory

Version Control

Checkout a project from a version control repository

Cancel

Choose the option *Version Control* option. In the next window that opens, choose *Git*.

[Back](#)

Create Project from Version Control

Git

Clone a project from a Git repository

Subversion

Checkout a project from a Subversion repository

[Cancel](#)

In the final window, paste the URL for your GitHub repo in the first text box. The middle text box should auto-fill with your repo name: `student_<last_name>`. The last text box is where you want to store your repo. On my computer, it shows the Desktop. If you'd rather place your course files in another place on your computer (*e.g.* a *projects* folder or maybe a *class* folder), then use the *Browse* button to select a new location. **The main thing is to remember where you saved it!** Once you're satisfied, click the *Create Project* button.

 Back

Clone Git Repository

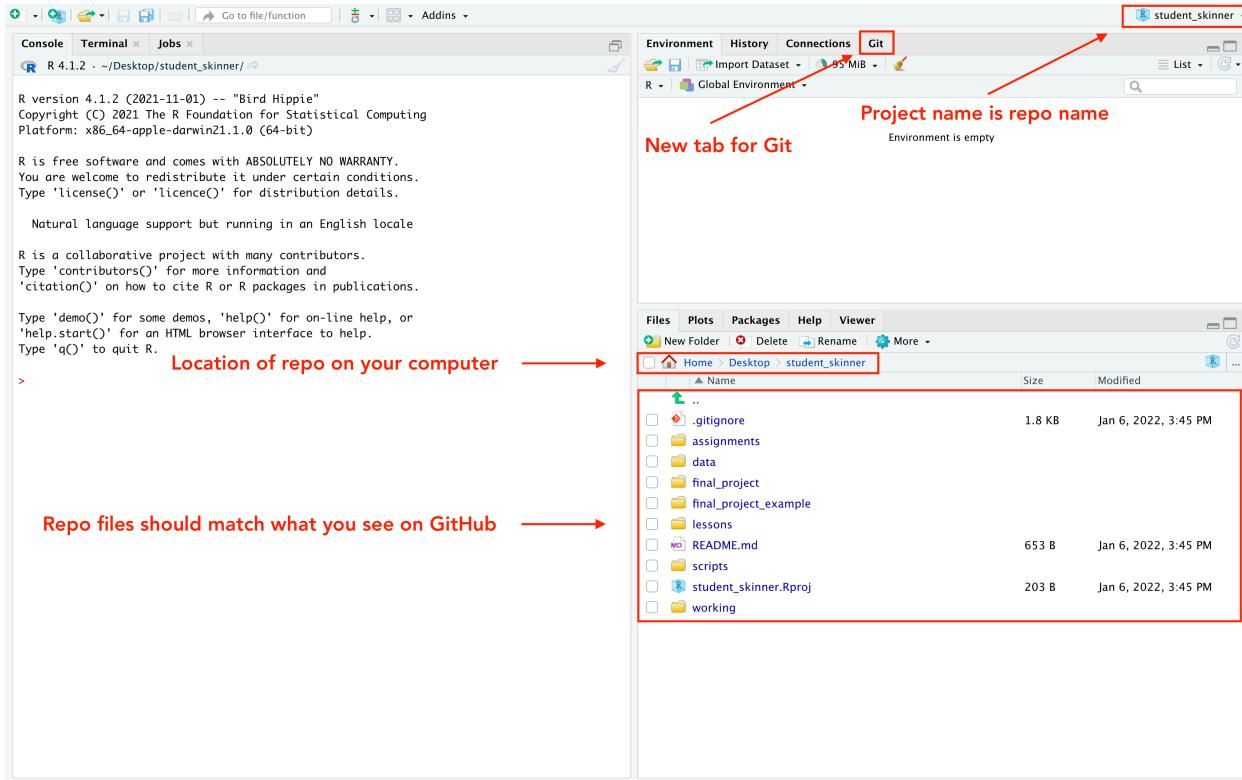

Repository URL:

Project directory name:

Create project as subdirectory of:

 Open in new session

If everything works, you'll see a drop down window that looks like it's doing some work with files. It will quickly close and RStudio will look like it is restarting, when it reopens, you should see your repo files in the bottom right pane, a new tab that says *Git*, and your repo name in the upper right as the new project name. You are now ready to work with your class files!

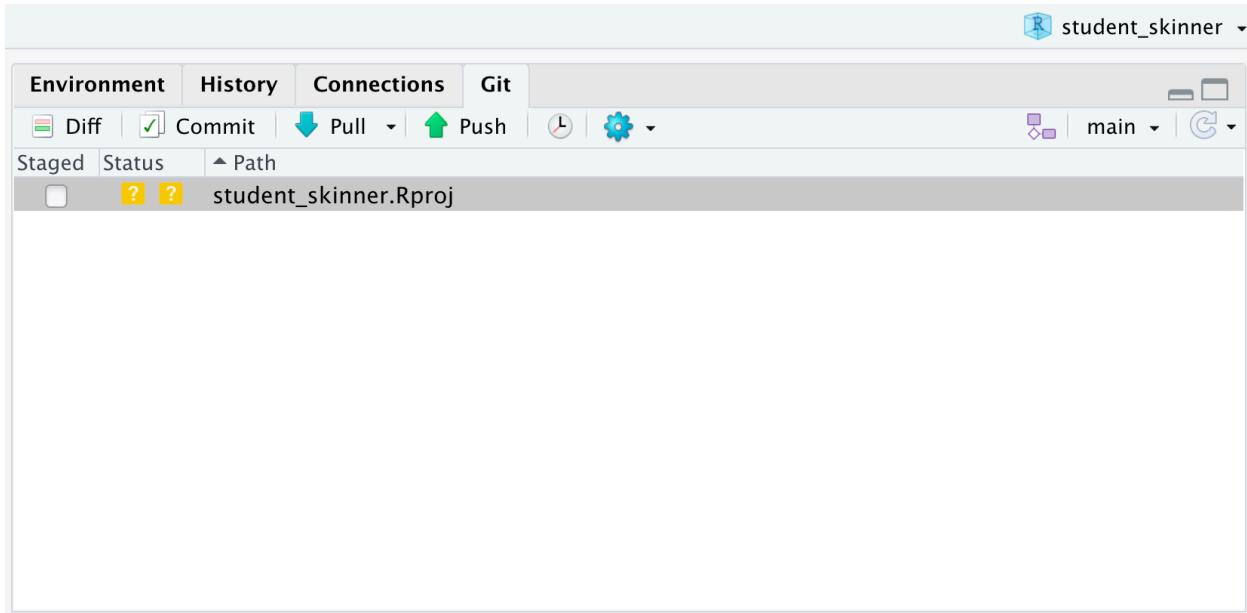

Staging/adding, committing, and pushing files from your computer to GitHub

There is nothing special about working in a git directory compared to a normal directory: you still open your files, edit them, and save as normal. The difference is that along the way, you take an extra step that involves:

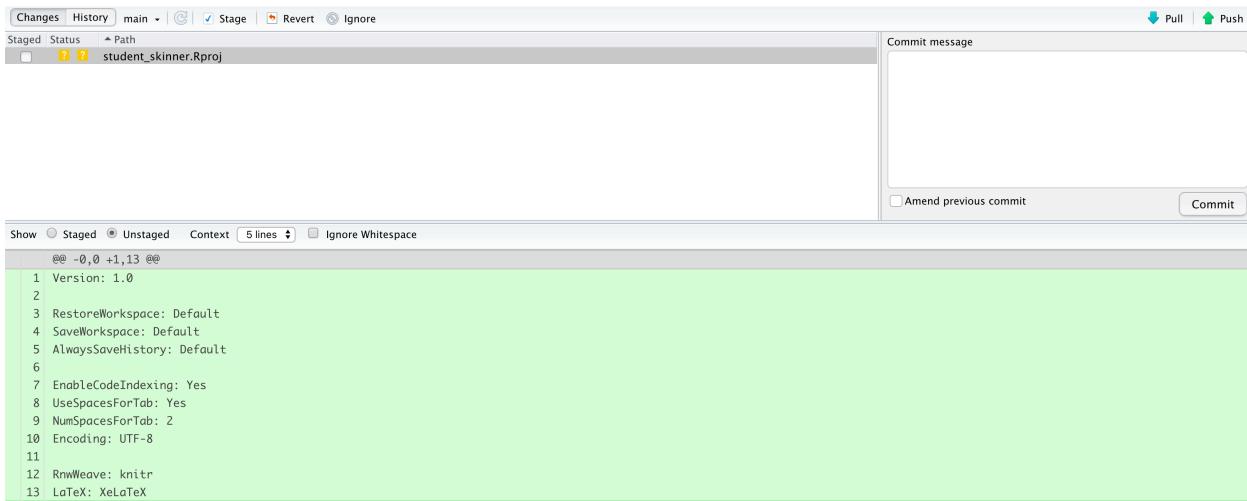

1. *Staging/adding* your files (telling git to pay attention to the changes you've made)
2. *Committing* your files (confirming that you want git to store your changes in your local repository)
3. *Pushing* your changes (copying changes to your local repository to your remote repository — GitHub)

If you click on the *Git* tab, you'll see a new file listed with some boxes next to it.

This particular file is a settings file and not that important for us, but it will be good to use as an example. If you want to see information about the file, click the *Diff* button on the far left, just under the *Environment* tab.

A new window will open. The bottom window shows the changes made to the file. Lines with additions are in green; lines with subtractions are in red. Because this is a new file, the entire text is green.

If you click on the *History* button, you can see the history of changes to the repo. There's not much right now, but over time, the history can be *very* helpful for finding deleted code or pinpointing when a bug was introduced.

Commit 2: Init course repo

Going back by clicking on *Changes* window, let's stage/add our file, commit it, and push it.

Stage/add

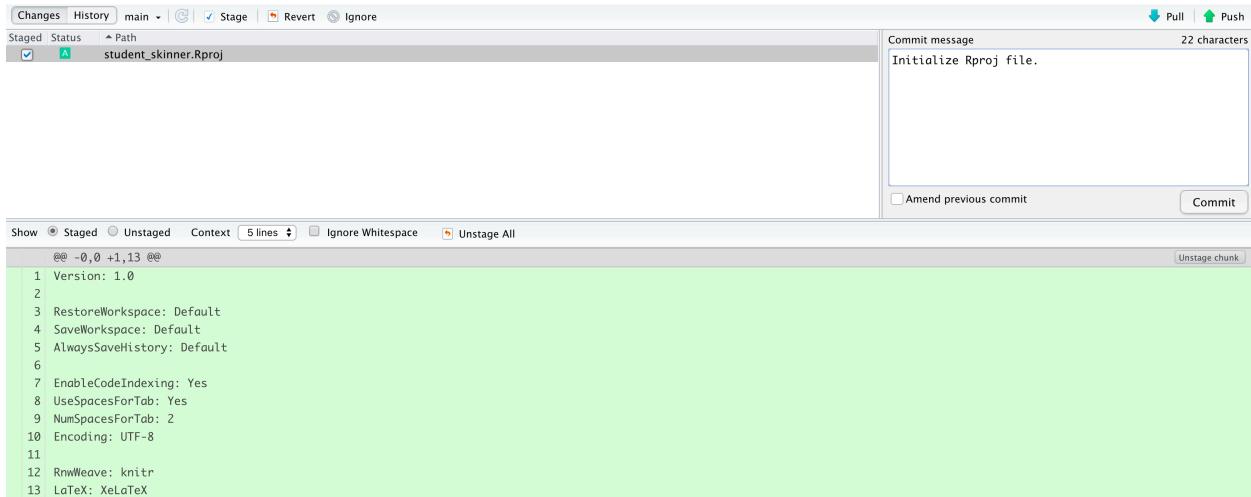

To stage/add a file, click the box next to the file name. You'll notice that the two boxes under the *Status* header become a single box with an "A" in it for **Add**.

The screenshot shows a Git commit interface. At the top, there are tabs for 'Changes' (selected), 'History', and 'main'. Below the tabs are buttons for 'Stage', 'Revert', and 'Ignore'. A blue header bar indicates that 'student_skinner.Rproj' is the selected file. On the right side, there is a 'Commit message' field with a 'Commit' button below it. There is also an 'Amend previous commit' checkbox. At the bottom left, there are buttons for 'Show', 'Staged' (selected), 'Unstaged', 'Context', '5 lines', 'Ignore Whitespace', and 'Unstage All'. The main area displays a diff view with the following content:

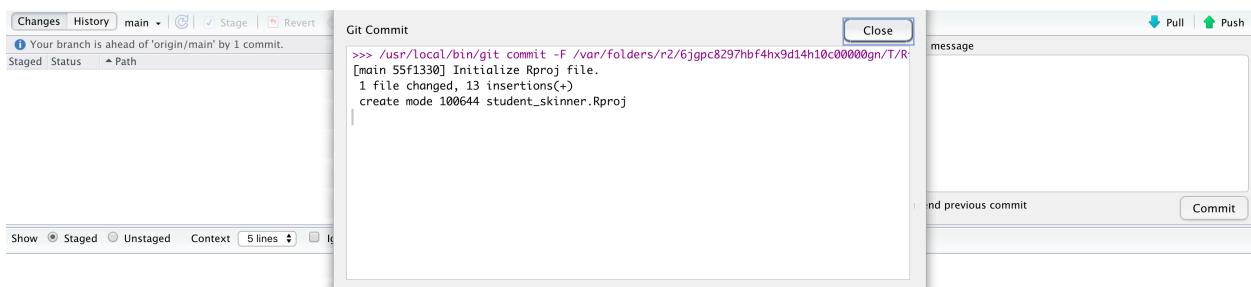

```

13 LaTeX: XeLaTeX
```

Commit

Next, you need to **Commit** the changes to the local repository. Do this by writing a message in the box on the right. You can write whatever you want, but per the suggestions above, I recommend something short and informative. Once you're done, click the *Commit* button.

You'll see a drop down menu telling you what has happened. At first this can seem like nothing, but over time, you'll get the hang of the messages. This tells you that 1 file (our `Rproj` file changed with 13 new lines (if there were deletions, it would say that, too). You can close this out.

After closing, notice that you don't see the file name any more or the changes in the bottom panel. However, there is new line towards the top left that tells you "Your branch is ahead of origin/main by 1 commit." *origin/main* is the git name of your remote repo: *origin* is the remote (GitHub) and *main* is the specific branch (we will only use the "main" branch in this course). In other words, your local repo has changes that are one step ahead of what's on GitHub. Time to sync them up!

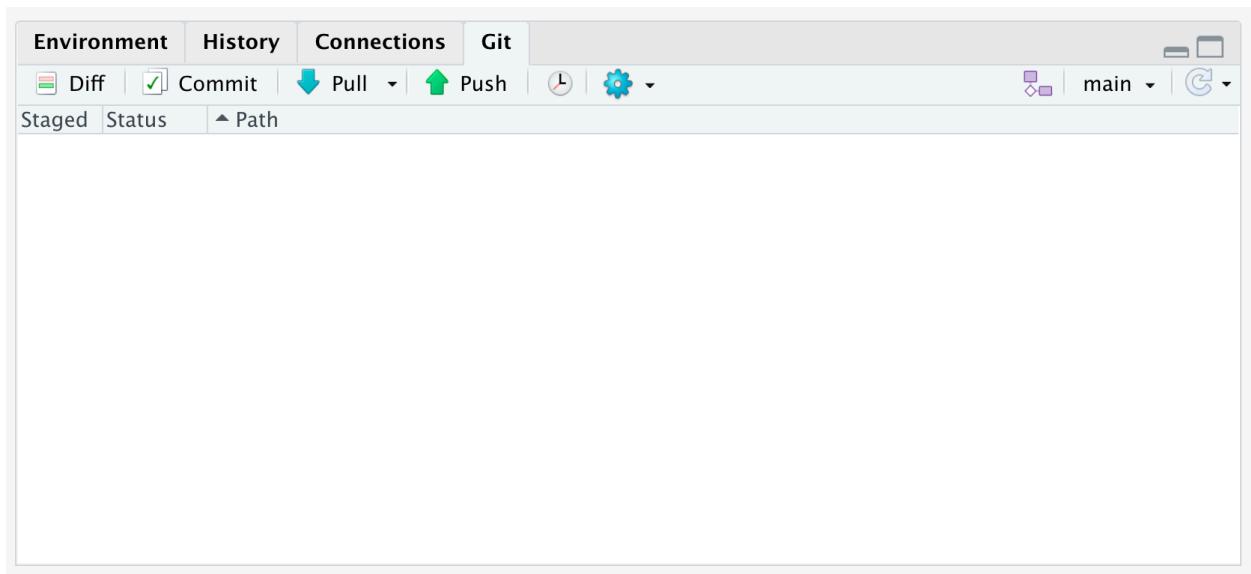

Push

Pushing the changes to GitHub is simple: just click the *Push* button in the far upper right (up arrow). Once again, you'll get a drop down window with messages from git. There's no error (it'll let you know), so you can close the window.

When you go back to the main RStudio window, you'll notice that file is no longer listed in the *Git* tab. Should you make changes to it, it will reappear. Similarly, any files in your local repo that you change, add, or delete will show up here.

If you want to confirm that the push worked, go to your repo at GitHub. If you can see the new file and the commit message, then you know your changes have made it to your GitHub repo. Importantly for this course, if you see the changes on GitHub, that means I can see them. Conversely, if you don't see the changes on GitHub, then I can't see them. Double check!

Pulling down changes from GitHub

Closing the loop, you also need to **pull** down changes from GitHub. In general, this is necessary when you are using multiple computers or working with a collaborator. For this course, you'll need to pull down updates and comments I make to your repo.

To pull, all you need to do is click the *Pull* button in the *Git* tab (with the down arrow).

If there's nothing new, you'll get a message like this. If so, you're good to go!

If there are changes, you'll be informed of those and you'll see them reflected in your local files. If there's a new file, you'll see it appear in your local directory. If a file is deleted, it will be removed from your local directory. If there were any changes in a file, you'll see them when you next open the file.

Committing changes before pulling down

One thing that catches new (and experienced!) git users is forgetting to stage/add and commit changes **before** pulling down new changes from the remote repo. If you try to pull from GitHub and there's a change to a file you have changed but haven't add/stage + committed, the pull won't work. It's annoying, but it's actually a nice feature: this prevents changes that you aren't tracking and therefore can't recover.

If this happens, stage/add and commit your local changes and then pull. If you have made changes that don't align with the new changes you just pulled down, you'll end up with a merged file. It can look messy, but it's totally fixable. If this happens and you have trouble, let me know.

Final note about git and this course

By construction of the scripts I use to build this course¹⁰, I have the ability to overwrite files you use. That said, I will only overwrite stuff that I put in there, like lessons, assignments, class scripts, etc. I will never overwrite anything you add. Also, I will not overwrite anything you put in the `working` folder. That's yours.

If you want to, for example, take notes in class scripts using comments (a very good idea), then simply rename the script. For example, you could rename the `intro_r.R` script to `intro_r_notes.R`. That way, when I update your repo, you won't lose your notes when `intro_r.R` is reset.

¹⁰<https://www.btskinner.io/grm/>
